# B(E2) VALUE OF ${ }^{82} \mathrm{Se},{ }^{84} \mathrm{Kr}$ AND ${ }^{86} \mathrm{Sr}$ ISOTONES FOR N=48 BY USING INTERACTING BOSON MODEL-1. 

Jobaidul Islam<br>Md. Didarul Islam Bhuyan<br>Obaydur Rahman<br>Department of Physics, Mawlana Bhashani Science and Technology University, Santosh, Bangladesh<br>\section*{Md. Habibur Rahman}<br>Department of Physics, Shah Jalal University of Science \& Technology, Bangladesh

#### Abstract

The reduced transition probability B(E2) $\downarrow$ of ${ }^{82} \mathrm{Se},{ }^{84} \mathrm{Kr}$ and ${ }^{86} \mathrm{Sr}$ isotones has been studied by using the Interacting Boson Model-1(IBM-1). Using this model the reduced transition probabilities $\mathrm{B}(\mathrm{E} 2)$ of these isotones have been calculated for the gamma transition from $8^{+} \rightarrow 6^{+}, 6^{+} \rightarrow 4^{+}, 4^{+} \rightarrow$ $2^{+}$and $2^{+} \rightarrow 0^{+}$states. For the first $4^{+}$and $2^{+}$excited states, the excitation energy ratio ( $\mathrm{R}_{4 / 2}$ ) has been also calculated.

Keywords: Reduced transition probabilities, ${ }^{82} \mathrm{Se},{ }^{84} \mathrm{Kr}$ and ${ }^{86} \mathrm{Sr}$ isotones, IBM-1.

## 1. Introduction

Arima and Lanchello has invented the Interaction Boson Model-1(IBM-1) (F Iachello and A Arima, 1975; A Arima and F Iachello, 1975). This model is helpful to describe the nuclear structure predicting the lowlying states. In this model the first approximation is only pairs with angular momentum $\mathrm{L}=0$ (called s-bosons) and $\mathrm{L}=2$ (called d-bosons) are considered. This model is also associated with an inherent group of structure, which allows the limiting symmetries called $\mathrm{U}(5), \mathrm{SU}(3)$ and $\mathrm{O}(6)$ ( F Iachello and A Arima, 1975; A Arima and F Iachello, 1975; R Kumar et al., 2010)

In the previous time, $\pi g_{9 / 2}^{-4}$ configurations for the $\mathrm{Z}=50$ closed shell, the yrast states $I^{\pi}=8^{+}$in $Z=46$ isotopes were investigated. The investigation for even-even nuclei $\mathrm{Z}=46$, which have been studied both theoretically and
experimentally because they exist near the magic number 50 (Y B Wang and J Rissanen, 2012; R Krucken et al., 2001; K B Moore et al., 1999; X O Zhang et al., 2001; H Hua et al., 2003).

Neutron rich nuclei are particularly interesting since they might excess of neutron. The yrast state up to $\mathrm{I}^{\pi}=8^{+}$in $\mathrm{N}=48$ isotones can be ascribed to the two-hole state $v g_{g / 2}^{-2}$ for the $\mathrm{N}=50$ close shell. Neutron rich nuclei study is more important because the configurations $\mathrm{vg}_{9 / 2}^{-2}$ are closer than that of $\pi g_{9 / 2}^{-4}$ to the magic number 50. Recently, Abdullah et. al has studied the reduce transition probability $\mathrm{B}(\mathrm{E} 2) \downarrow$ and other parameters of $8^{+}$ isomers even-even nuclei from ${ }^{76} \mathrm{Ni}$ to ${ }^{94} \mathrm{Pd}$ for $\mathrm{N}=48$ for the energy $8^{+} \rightarrow 6^{+}$ ( H. Y. Abdullah et al, 2001). In this study, we have calculated the reduced transition $\mathrm{B}(\mathrm{E} 2)$ of the $8^{+}$isomers in the $\mathrm{N}=48$ isotones ${ }_{34}^{82} \mathrm{Se}_{48},{ }_{36}^{84} \mathrm{Kr}_{48}$, ${ }_{38}^{86} S r_{48}$ for the $8^{+} \rightarrow 6^{+}, 6^{+} \rightarrow 4^{+}, 4^{+} \rightarrow 2^{+}$and $2^{+} \rightarrow 0^{+}$states using IBM-1.

## 2. Theoretical calculation

### 2.1 Reduced transition probabilities B(E2)

We have calculated the reduced transition probabilities $\mathrm{B}(\mathrm{E} 2)$ from the reduced matrix elements of the E 2 transition operator $\left(\mathrm{T}^{\mathrm{E} 2}\right)$ of the form (A Arima and F Iachello, 1975).
$T^{E 2}=\alpha_{2}\left[d^{*} s+s^{*} d\right]^{(2)}+\left[d^{*} d\right]^{(2)}$
Where $\alpha_{2}$ is the role of effective boson charge and the low -lying levels of even-even ( $L_{i}=2,4,6,8, \ldots$ ) decay E2 transition to the lower yrast states with $L_{f}=L_{i}-2$. IBM-1 gives the reduced transition probabilities $\mathrm{B}(\mathrm{E} 2) \downarrow$ for the $\mathrm{U}(5)-\mathrm{O}(6)$ (O Scholten and F Iachello, 1978) by
$B(E 2 ; L+2 \rightarrow L) \downarrow=\frac{1}{4} \alpha_{2}^{2}(L+2)(2 N-L)$
Where N is the boson number and L is the translate state. The boson number N is equal to half the number f valence nucleons. Here $\alpha_{2}^{2}$ has been determined from the experimental value $\mathrm{B}(\mathrm{E} 2)$ of transition $\left(8^{+} \rightarrow 6^{+}\right)$. The parameter $\alpha_{2}^{2}$ has been also calculated for each isotones which means square of the effective charge. The calculated value is used for the transition of $8^{+}$ $\rightarrow 6^{+}, 6^{+} \rightarrow 4^{+}, 4^{+} \rightarrow 2^{+}$and $2^{+} \rightarrow 0^{+}$states.

## 3. Result and discussion

Table shows the boson number, transition levels and the downward reduced transition probabilities $\mathrm{B}(\mathrm{E} 2) \downarrow$ for the $8^{+} \rightarrow 6^{+}, 6^{+} \rightarrow 4^{+}, 4^{+} \rightarrow 2^{+}$ and $2^{+} \rightarrow{ }^{0+}$ states of ${ }_{34}^{82} S e_{48},{ }_{36}^{84} \mathrm{Kr}_{48},{ }_{38}^{86} \mathrm{Sr}_{48}$ isotones. The pair of valence nucleons is boson. And the boson number is calculated as the sum of pairs of
valence nucleons. Total bosons is $\mathrm{N}=\left(\mathrm{N}_{\mathrm{P}}+\mathrm{N}_{\mathrm{n}}\right) / 2=\mathrm{n}_{\pi}+\mathrm{n}_{v}$. Where $\mathrm{N}_{\mathrm{p}}$ is valence proton and $\mathrm{N}_{\mathrm{n}}$ is valence neutron. $\mathrm{n} \pi$ is the pair of valence proton and $n v$ is pair of valence neutron. From the experimental value of B(E2) $\downarrow$ from $8+\rightarrow 6+$ transition, the reduced transition probabilities of $6^{+} \rightarrow 4^{+}, 4^{+}$ $\rightarrow 2^{+}, 2^{+} \rightarrow 0^{+}$transitions of ${ }_{34}^{82} S e_{48},{ }_{36}^{84} K r_{48},{ }_{38}^{86} S r_{48}$ isotones using IBM-1 and shown in the Table.
$3.1 \mathrm{R}_{4 / 2}$ classification
The excitation energies ratio of first $4^{+}$and first $2^{+}$states is:
$R_{4 / 2}=\frac{E\left(4_{1}^{+}\right)}{E\left(2_{1}^{+}\right)}$
This ratio classifies the even-even nuclei (F Iachello and A Arima, 1987). The limit of the ratio $2.0 \sim 2.4$ is an harmonic vibrator $U(5), 2.4 \sim 2.7$ represents the limit of $\mathrm{O}(6), 2.7 \sim 3.0$ shows the transitional nuclei and the limit $3.0 \sim 3.3$ indicates an axially symmetric rotor $\operatorname{SU}(3)$. The variation of R4/2 values are plotted as a function of even-even proton numbers of ${ }_{34}^{82} \mathrm{Se}_{48}$ , ${ }_{36}^{84} K r_{48},{ }_{38}^{86} S r_{48}$ isotones in figure.
Table: Reduced transition probability B(E2) $\downarrow{ }_{\text {in }}{ }^{82} S e_{48},{ }_{36}^{84} K r_{48},{ }_{38}^{86} S r_{48}$ nuclei (Habibur Rahman, 2010).

## 4. Conclusion

Here we have used the IBM-1 to calculate the reduced transition probability $\mathrm{B}(\mathrm{E} 2) \downarrow$ for the $\mathrm{B}(\mathrm{E} 2) \downarrow$ in ${ }^{34} S e_{48},{ }_{36}^{84} K r_{48},{ }^{86} S r_{48}$ nuclei. The analytical calculation of IBM-1 $\mathrm{B}(\mathrm{E} 2) \downarrow$ values of these isotones have been performed in $\mathrm{U}(5)-\mathrm{O}(6)$ character. This result is very much helpful for compiling the nuclear data table.
